40 The starting compounds of the formula (2) in the above Reaction Scheme-1 include novel compounds and can be prepared by the processes as shown in the following Reaction Scheme-3.

[Reaction Scheme-3]

wherein A, B, D, R¹, k, l, m and X are as defined above, and D' is a lower alkylene having one less carbon atom than that of D in the main chain, and p is 0 or 1.

30 According to the above Reaction Scheme-3, the compound of the formula (5) can be prepared by reducing the compound of the formula (4).

The reducing reaction can be carried out by a conventional method, which conditions may vary depending on the kinds of the substituents of R¹ and the group B of the compound (4).

That is, in case of converting the starting compound (4) wherein the group B is a carbonyl group into 35 the corresponding compound (5) wherein said group B is maintained as it stands, the reducing reaction is preferably carried out by previously esterifying the compound (4) or previously converting the compound (4) into an acid halide, followed by the reducing reaction.

The esterification is carried out by reacting the compound (4) with an alcohol in an appropriate inert solvent in the presence of an acidic catalyst. The inert solvent used therein includes various solvents which 40 do not give any bad effect on the reaction, for example, ethers such as diethyl ether, THF, dioxane, etc.; halogenated hydrocarbons such as dichloromethane, dichloroethane, chloroform, etc.; aromatic hydrocarbons such as benzene, toluene, xylene, etc.; aliphatic hydrocarbons such as hexane, heptane, etc.; alcohols such as methanol, ethanol, propanol, etc.; or a mixture of these solvents. The acidic catalyst includes, for example, Lewis acids such as aluminum chloride, stannic chloride, titanium tetrachloride, boron trichloride, 45 boron trifluoride-ethyl ether complex, zinc chloride, etc.; inorganic acids such as hydrochloric acid, nitric acid, sulfuric acid, etc.; organic acids such as trichloroacetic acid, trifluoroacetic acid, methanesulfonic acid, acetic acid, etc.; acid type ion exchange resins; and the like.

The alcohol to be reacted with the compound (4) includes methanol, ethanol, propanol, etc, which can also act as a solvent. The alcohol is usually used at least in an equimolar amount, preferably in an amount 50 of about 1 to 30 moles to 1 mole of the compound of the formula (4), and the reaction is usually carried out at room temperature to a reflux temperature of the solvent, for about 1 to 72 hours, preferably about 3 to 24 hours.

The subsequent reducing reaction is carried out by a conventional method, for instance, by using an appropriate reducing agent in an appropriate solvent. The solvent includes the conventional inert solvents, 55 for example, ethers such as diethyl ether, THF, dioxane, etc.; aromatic hydrocarbons such as benzene, toluene, xylene, etc.; aliphatic hydrocarbons such as hexane, heptane, etc.; alcohols such as methanol, ethanol, propanol, etc.; and the like, or a mixture of these solvents. The reducing agent includes, for example, metal hydrides such as sodium cyanoboron hydride, sodium boron hydride, lithium aluminum

hydride, etc.; borane, and the like, preferably sodium boron hydride which is used while adding thereto methanol dropwise. These reducing agents are usually used in an amount of about 0.1 to 5 moles, preferably about 0.5 to 2 moles, to 1 mole of the starting ester, and the reducing reaction is usually carried out at about -50°C to a reflux temperature of the solvent for about 10 minutes to about 24 hours, preferably about 1 to 5 hours. When the reducing reaction is carried out while adding dropwise methanol, the methanol is usually used in an amount of about 1 to 50 moles, preferably about 4 to 20 moles, to 1 mole of the reducing agent.

Besides, in the process of previously converting the compound of the formula (4) into an acid halide, followed by subjecting to the reducing reaction, the converting reaction into an acid halide is carried out by a conventional method. In more detail, the reaction is carried out by using a halogenating agent such as a halogen molecule (e.g. chlorine, bromine, iodine, etc.), a thionyl halide (e.g. thionyl chloride, thionyl bromide, etc.), and the like, in an appropriate solvent such as halogenated hydrocarbons (e.g. methylene chloride, 1,2-dichloroethane, chloroform, etc.), aromatic hydrocarbons (e.g. benzene, xylene, toluene, etc.), ethers (e.g. THF, dioxane, etc.), and the like. The above halogenating agent is used at least in an equimolar amount, preferably in an amount of 1 to 2 moles, to 1 mole of the starting compound. The reaction is usually carried out at about -10 to 150°C , preferably at about 0°C to about 100°C , for about 1 to 20 hours, preferably about 1 to 10 hours.

The reducing reaction of the acid halide thus prepared is carried out by a conventional method, for example, with a conventional reducing agent in an appropriate solvent. The solvent includes various conventional solvents, for example, ethers such as diethyl ether, THF, dioxane, etc.; halogenated hydrocarbons such as dichloromethane, dichloroethane, chloroform, carbon tetrachloride, etc.; aromatic hydrocarbons such as benzene, toluene, xylene, etc.; aliphatic hydrocarbons such as hexane, heptane, etc.; aprotic polar solvents such as DMF, DMSO, HMPA, etc.; and the like, or a mixture of these solvents. The reducing agent includes, for example, metal hydrides such as sodium cyanoboron hydride, sodium boron hydride, lithium aluminum hydride, and the like, preferably sodium boron hydride. These reducing agents are usually used in an amount of about 0.1 to 5 moles, preferably about 0.5 to 3 moles, to 1 mole of the starting acid halide, and the reaction is usually carried out at about -50°C to a room temperature, preferably about -10°C to about 10°C , for about 10 minutes to about 8 hours, preferably about 30 minutes to about 2 hours.

In the Reaction Scheme-3, the starting compound of the formula (4) wherein the group B is a carbonyl group may be converted into the compound of the formula (5) by simultaneously reducing the group B into a methylene group together with reduction of the carboxyl group. The reducing reaction can be carried out, for example, in above-mentioned various inert solvent with a reducing agent, for example, metal hydrides such as sodium cyanoboron hydride, sodium boron hydride, lithium aluminum hydride, etc.; borane, and the like, preferably lithium aluminum hydride. These reducing agents are usually used in an amount of about 0.1 to 100 moles, preferably about 1 to 10 moles, to 1 mole of the starting compound, and the reaction is usually carried out at about -20 to 180°C , preferably about 0 to 100°C , for about 10 minutes to about 24 hours, preferably about 3 to 20 hours.

In the Reaction Scheme-3, the reducing of carboxyl group of the compound of the formula (4) wherein the group B is a methylene group is carried out in the same manner as in case of converting the starting compound (4) wherein the group B is a carbonyl group into the corresponding compound (5) wherein said group B is maintained as it stands, by previously esterifying the compound (4) or previously converting the compound (4) into an acid halide, followed by the reducing reaction as mentioned hereinabove.

Besides, in the Reaction Scheme-3, when a compound of the formula (4) wherein R^1 is a hydroxy group is used in the reaction of esterifying the compound (4) and then reducing to give the compound (5), the esterified compound may be etherified to convert it into the corresponding compound wherein R^1 is a lower alkoxy group or a phenyl(lower)alkoxy group having optionally a substituent of a halogen atom or a lower alkyl group on the phenyl ring and thereafter subjecting to the reducing reaction. The above reaction of converting the R^1 group (i.e. etherifying reaction) can be carried out under the same conditions as in the ether-bond forming reaction in the above Reaction Scheme-1.

The desired compound of the formula (5) can be obtained as above.

According to the Reaction Scheme-3, the hydroxy group of the compound of the formula (5) thus obtained is converted into the X group to give the desired compound of the formula (2).

The converting reaction of the compound (5) having a hydroxy group into the compound (2) having the X group is usually carried out by reacting the compound (5) with a sulfonic acid compound or a reactive derivative at the sulfo group thereof or with a halogenating agent in a solvent.

[Reaction Scheme-5]

wherein A, B, D', R¹, k, l, m, p and X are as defined above.

According to the above Reaction Scheme-5, the compound of the formula (2a) is reacted with a cyanide compound to give the compound of the formula (8), and then the compound (8) is hydrolyzed to give the desired compound of the formula (4).

The reaction of preparing the compound (8) from the compound (2a) is usually carried out in an appropriate inert solvent by using a cyanide compound. The inert solvent used therein includes, for example, ethers such as dimethyl ether, diethyl ether, THF, dioxane, anisole, etc.; aromatic hydrocarbons such as benzene, toluene, xylene, etc.; alcohols such as methanol, ethanol, propanol, etc.; aprotic polar solvents such as DMF, DMSO, HMPA, etc.; and the like. The cyanide compound is usually used in an amount of about 1 to 5 moles, preferably about 1 to 2 moles, to 1 mole of the compound of the formula (2a). The above reaction is usually carried out at about 0 to 200 °C, preferably at room temperature to about 120 °C, for about 1 to 72 hours, preferably about 3 to 24 hours.

The subsequent hydrolysis can be carried out under the same conditions as in the de-esterification as shown in the above Reaction Scheme-2.

The compound of the formula (5) in the above Reaction Scheme-3 may also be prepared by other processes as follows.

[Reaction Scheme-6]

wherein D' , R^1 , k , m and p are as defined above, A' is a lower alkylene group having one less carbon atom in the main chain than that of the group A or a lower alkyleneoxy group having one less carbon atoms in the main chain than that of the group A , r is 0 or 1, and R^3 is a lower alkyl group.

According to the above Reaction Scheme-6, the carboxylic acid compound of the formula (9) and the compound of the formula (10) are reacted by a conventional amido bond producing reaction to give the compound of the formula (11) and then the compound of the formula (11) is subjected to a reducing reaction to give the desired compound of the formula (5b).

The amido bond producing reaction can easily be carried out by the conventional various processes, for example, a mixed acid anhydride process, an activated ester process, a process using a condensation agent, a carboxylic acid anhydride process, a process of carrying at a high temperature under high pressure, an acid halide process, and the like.

The acid halide process is explained in detail below. This process can be carried out by converting the compound of the formula (9) into an acid halide compound, and reacting the acid halide with the compound of the formula (10) in an appropriate solvent in the presence of a dehydrohalogenation agent. The dehydrohalogenation agent includes conventional agents, for example, sodium hydrogen carbonate, sodium carbonate, potassium carbonate, pyridine, triethylamine, and the like. The solvent includes also conventional ones, for example, benzene, chloroform, methylene chloride, dioxane, THF, and the like. The acid halide used in the above reaction is usually used at least in about equimolar amount, preferably in an amount of about 1 to 3 moles, to 1 mole of the compound (10). The reaction temperature is usually in the range of -30 to 100°C , preferably room temperature to about 80°C , and the reaction is usually completed in about 20 minutes to about 20 hours.

The reaction for preparing the compound of the formula (5b) from the compound (11) thus obtained is carried out under the same reducing reaction conditions as in the reducing reaction of the compound of the formula (4) wherein the group B is a carbonyl group to prepare the compound of the formula (5) wherein B is a methylene group as shown in the above Reaction Scheme-3.

The compounds of the formula (3) in the above Reaction Scheme-1 include also novel compounds, which can be prepared by a process as shown in the following Reaction Scheme-7.

[Reaction Scheme-7]

wherein R^4 is hydrogen atom or a lower alkyl group.

According to the above Reaction Scheme-7, the compound of the formula (12) is reacted with an aliphatic carboxylic acid anhydride of the formula (13) or an alkali metal salt (e.g. sodium or potassium salt) thereof with heating (Perkin reaction) to give the compound of the formula (3a).

In this reaction, the compound (13) or a salt thereof is usually used in an amount of about 1 to 100 moles, preferably about 1 to 20 moles, to 1 mole of the compound of the formula (12). This reaction is usually carried out at about 0 to 200°C, preferably at room temperature to about 150°C, for about 30 minutes to about 96 hours, preferably for about 1 to 48 hours.

The compounds of the formula (1) can be converted into various compounds wherein R^1 and E have various groups as mentioned hereinabove.

Besides, among the compounds of the formula (1) and the intermediate compounds for preparing the same as shown in the above reaction schemes, the compounds having the following R^1 groups can be converted into the corresponding desired compounds or intermediates having the desired R^1 groups by the following various reactions.

That is, the compounds wherein R^1 is a hydroxy group can be converted into the compounds wherein R^1 is a lower alkylsulfonyloxy group by subjecting it to the reaction as shown in the above Reaction Scheme-3.

The compounds wherein R^1 is a lower alkanoylamino group can be converted into the compounds having the corresponding amino group by a conventional amide hydrolysis reaction.

The hydrolysis can be carried out, for example, by using an acid catalyst as used in the de-esterification reaction as shown in the above Reaction Scheme-2 in an appropriate inert solvent. The inert solvent used therein includes various solvents which do not give any bad effect on the reaction, for example, ethers such as dimethyl ether, diethyl ether, THF, dioxane, anisole, etc.; halogenated hydrocarbons such as dichloromethane, dichloroethane, chloroform, carbon tetrachloride, etc.; aromatic hydrocarbons such as benzene, toluene, xylene, etc.; aliphatic hydrocarbons such as hexane, heptane, octane, etc.; alcohols such as methanol, ethanol, propanol, etc.; aprotic polar solvents such as DMF, DMSO, HMPA, etc.; water; and the like, or a mixture of water with the above organic solvents, among which preferred one is alcohols which have the same alkyl group as the group R^2 in the starting compounds. The reaction temperature and reaction time are the same as those in the above-mentioned de-esterification reaction. By such a hydrolysis, the desired compounds wherein R^1 is an amino group can be obtained.

In the above hydrolysis reaction, when the solvent used therein is a solvent other than the alcohols which have the same alkyl group as the group R^2 in the starting compounds, de-esterification of R^2 group occurs simultaneously with the deacylation of the R^1 group to give the corresponding compounds wherein R^1 is an amino group and R^2 is a carboxyl group. This reaction can also be used for the preparation of the desired compounds of the present invention and the intermediates.

The compounds wherein R^1 is a phenyl(lower)alkoxy(lower)alkoxy group can be converted into the corresponding compounds wherein R^1 is a hydroxy(lower)alkoxy group by subjecting to the same catalytic reduction as used in the reaction shown in Reaction Scheme-1.

The compounds wherein R^1 is a hydroxy group can be converted into the corresponding compounds wherein R^1 is the desired groups by reacting the compounds with a compound of the formula: $R-X$ (wherein R is the same groups as R^1 other than hydroxy group and X is a halogen atom) under the same conditions as in the ether bond-forming reaction as shown in the above Reaction Scheme-1. In this reaction, the compound of the formula: $R-X$ is usually used in an amount of about 1 to 30 moles, preferably about 1 to 10 moles, to 1 mole of the starting compound.

Moreover, the compounds wherein R^1 is a hydroxy group can also be converted into the desired compounds wherein R^1 is a hydroxy-substituted lower alkoxy group by reacting them with an appropriate epoxy compound (i.e. an alkene oxide). The reaction is carried out, for example, in an appropriate inert solvent in the presence of a basic compound. The inert solvent used therein includes various solvents which

do not give any bad effect on the reaction, for example, ethers such as diethyl ether, THF, dioxane, etc.; halogenated hydrocarbons such as dichloromethane, dichloroethane, chloroform, carbon tetrachloride, etc.; aromatic hydrocarbons such as benzene, toluene, etc.; amines such as pyridine, piperidine, triethylamine, etc.; aliphatic hydrocarbons such as hexane, heptane, etc.; alcohols such as methanol, ethanol, propanol, etc.; aprotic polar solvents such as DMF, DMA, DMSO, HMPA, etc.; carbon disulfide; and the like. The basic compound includes, for example, organic basic compounds such as tertiary amines (e.g. triethylamine, pyridine, etc.), inorganic basic compounds such as alkali metal carbonates (e.g. sodium carbonate, potassium carbonate, etc.), alkali metal hydrogen carbonates (e.g. sodium hydrogen carbonate, potassium hydrogen carbonate, etc.), alkali metal hydroxides (e.g. sodium hydroxide, potassium hydroxide, etc.), alkali metal alkoxides (e.g. sodium methoxide, sodium ethoxide, potassium methoxide, potassium ethoxide, potassium tert-butoxide, etc.), alkali metals (e.g. metal sodium, metal potassium etc.), and alkali metal hydrides (e.g. sodium hydride, etc.), and the like. The epoxy compound is usually used in an amount of about 1 to 100 moles, preferably about 1 to 30 moles, to 1 mole of the starting compound wherein R¹ is a hydroxy group, and the basic compound is usually used in an amount of about 0.01 to 10 moles, preferably about 0.1 to 3 moles, to 1 mole of the above starting compound. This reaction is usually carried out at about 0 to 200 °C, preferably at room temperature to about 120 °C, for about 5 hours to about 10 days, preferably about 1 to 7 days.

The compounds wherein R¹ is a hydroxy-substituted lower alkoxy group can be converted into the corresponding compounds wherein R¹ is a lower alkylsulfonyloxy(lower)alkoxy group by subjecting them to the same reaction as shown in Reaction Scheme-3.

The compounds wherein R¹ is a lower alkylsulfonyloxy(lower)alkoxy group or a halogen-substituted lower alkyl group can be converted into the corresponding compounds wherein R¹ is an imidazolyl(lower)-alkyl group or an imidazolyl(lower)alkoxy group respectively by reacting them with imidazole. This reaction can be carried out in a similar manner as in the ether bond-forming reaction as shown in Reaction Scheme-1. The compounds wherein R¹ is a halogen-substituted lower alkyl group used in the above reaction can easily be prepared by halogenating the corresponding compounds wherein R¹ is a lower alkyl group by a conventional halogenating process.

The compounds wherein R¹ is a hydroxy group can be converted into the corresponding compounds wherein R¹ is a tert-butoxy group by reacting them with O-tert-butyl-N,N'-dicyclohexylisourea under the following conditions. The alkylation reaction can be carried out in an appropriate solvent, for example, ethers such as diethyl ether, THF, dioxane, etc.; halogenated hydrocarbons such as dichloromethane, dichloroethane, chloroform, carbon tetrachloride, etc.; aromatic hydrocarbons such as benzene, toluene, xylene, etc.; aliphatic hydrocarbons such as hexane, heptane, etc.; aprotic polar solvents such as DMF, DMA, DMSO, HMPA, etc.; and the like. The O-tert-butyl-N,N'-dicyclohexylisourea is usually used in an amount of about 1 to 30 moles, preferably about 1 to 5 moles, to 1 mole of the compound wherein R¹ is a hydroxy group. The reaction is usually carried out at about 0 to 150 °C, preferably at room temperature to about 80 °C.

50 [Pharmacological test]

Test of effect on biosynthesis system of sterol or fatty acid by using rat liver slices:

55 In this test, male Wistar rats (weight; about 200 g) are killed and their livers are taken out and perfused with cold Krebs-Ringer bicarbonate buffer solution (hereinafter referred to KRB), and cut into small slices. Using the small liver slices, the test is carried out in the following manner referring to the following literatures.

Bortz, W. M. and Steele, L. A. (1973), Biochim. Biophys. Acta, 306, 85 - 94

Tsujita, Y., Kuroda, M., Shimada, Y., Tanzawa, K., Arai, M., Kaneko, I., Tanaka, M., Masuda, H., Tarumi, C., Watanabe, Y. and Fujii, S. (1986), *Biochim. Biophys. Acta*, 877, 50 - 60

That is to say, the above-mentioned small liver slices (100 mg) are weighed and added into the KRB (1 ml) containing [1 - 14 C] acetic acid (2 μ Ci/2 μ mol) and a prescribed amount of test compounds, and the mixture is reacted with shaking at 37° C for 2 hours under atmosphere of 95 % O₂/5 % CO₂. Thereafter, to the reaction mixture is added 15 % solution of sodium hydroxide in ethanol (1 ml), and further heated at 75° C for 2 hours. After cooling, petroleum ether (2 ml) is added to the mixture, and it is shaken and separated into layers. The petroleum ether layer (upper layer) is extracted. The petroleum ether layer is concentrated to dryness, and thereto digitonin solution (1 ml) is added and sterol is collected in the resulting precipitation fraction. This fraction is washed with diethyl ether and dissolved in acetic acid (1 ml), and the radioactivity of the sample is measured to determine the sterol biosynthesis activity.

On the basis of the value obtained in the control test, in which the above procedure is repeated except that no test compound is used, the concentration (μ M) of the test compound inhibiting 50 % of sterol biosynthesis activity is calculated, which is shown as 50 % inhibitory concentration.

On the other hand, hydrochloric acid is added into the lower layer obtained by extraction with petroleum ether in the above procedure, and the mixture is extracted with petroleum ether under an acidic condition, and the extract is concentrated, and then, the radioactivity is measured likewise to determine the fatty acid biosynthesis activity. Likewise as above, on the basis of the fatty acid biosynthesis activity obtained in the control test, 50 % fatty acid biosynthesis activity inhibitory concentration of the test compounds is determined.

Thus obtained results are showed in the following Table 1.
